Category:Computer-aided design software Category:AutodeskQ: How do I use a Java class with another Java class? In my big java project, there are two classes. Class A is the main class, and Class B is just some simple code that class A uses to work. I need to get the data from Class B into the main class. How would I do this? I thought I could just put Class B's class variables and methods into A, and I could call them from the main class, but I get an error when I do that. Thanks A: If your main class (class A) needs to use the functionality of class B, then your main class should use class B. Alternatively, it may be possible for your main class to load the class B functionality at runtime, but this is generally a bad idea. A: One way is to pass the object from A to B. Something like the following: public interface WrapperA { public WrapperB getB(); } public interface WrapperB { public void doSomething(); } public class A implements WrapperA { private WrapperB b = new WrapperB(); @Override public WrapperB getB() { return b; } } public class B implements WrapperB { public void doSomething() { System.out.println("Hello World!"); } } Then use the class A like you normally would. If you need to call the doSomething method on B when it is in A, you need to use the WrapperB when you call getB. Q: How to make a button respond to a change of a select element inside the same parent? My page currently looks like this: Test a b

AutoCAD is a useful software for the CAD industry. It is.The invention relates to a system for the continuous separation and gassing of recirculating baghouse dust to free dust from an exhaust stream. A baghouse dust collection system has a paper dust exhaust system for blowing off baghouse dust containing separated components from the baghouse or inlet to the baghouse which consists of an exhaust duct in which an exit-air flap is provided. In known dust collection systems the exit-air flap is situated in the duct and the baghouse dust containing separated components is blown directly through the duct to an exhaust location. In such systems the dust is blown directly from the baghouse on the baghouse dust receiving sheet to which the bags are attached. A considerable proportion of the dust is thus lost. To reduce the loss of dust it is possible to add a partition or a separate dust receiver. The addition of a partition also has the disadvantage of increasing the pathlength of the exhaust duct which in turn requires a larger cross section. In addition, it may be desirable to separate the exhausted air stream or dust stream in order to remove or reduce the dust content. For this, a filter is either used which is capable of filtering the dust from the exhaust air stream, or the dust is separated by such means that only a part of the dust passes through. There are a number of known apparatuses for separating dust and exhaust air from a dust collection system. An example of such an apparatus is disclosed in EP f678ea9f9e
